

Digital AV SDK – Record layouts & Content inventory

Release Version: 3.9

Digital-AV Software Development Kit provides the foundation for a fully working bible application, with no external dependencies. The SDK provides everything, including data with indexes. Be up and running in under an hour! Easily jumpstart your development by leveraging sources in the foundational releases.

Filename: AVX-Omega-3911.data

Total-Length: 19,650,967 [Windows says 19,651,015]

Content-Hash: 90B73F90B8AED72CEF0325411C00C4FE *(of AVX-Omega-3910.data // from AVX-Omega-3910.md5)*

The description of all content, artifact by artifact, is provided in the following pages of this document.

Directory Content (48 bytes per record)

The Digital-AV SDK (AV SDK) is entirely file based. There are zero dependencies and zero language bias (all programming languages can read a file). The Ω-Series SDK is derived from the earlier Z-Series SDK. The main difference is the Ω-Series uses a single content file, beginning with a content directory as depicted above (The Z-Series releases have multiples files and a separate inventory file similar to the directory). The directory identifies the content sections for easy deserialization. The first field is the label, followed by an offset, and a length (in bytes). It also includes record length: zero (0) indicates that the record is variable length; non-zero length means that the record is fixed length. Record count, and content hash [using MD5] are the final fields for each directory item.

The file format defined in this document pertains to the Ω-Series releases. Both Ω and Z series formats are similar, but not identical. Consequently, some formats that have been revised in the Ω-Series do not have corresponding revisions in the Z-Series SDK specification. In some sense, the Z-Series SDK is considered to be deprecated.

The most substantial content contained in the directory is that which is Written. It represents the stream of words for each verse of each chapter of each book of the KJV bible. These are not text files. Therefore, they are quite compact. Several fields are index lookups into other SDK content. In short, the collective content manifests an efficient database of word embeddings that resides compactly in RAM.

The first field of Written content contains Strong's numbers¹. These are a numeric representation of the original Hebrew/Greek words from which the sacred text was originally translated.

Hebrew | Greek

Strong's #1	Strong's #2	Strong's #3	Strong's #4
1 st numeric	2 nd numeric	3 rd numeric	4 th Strong's #

¹ Refer to the Strong's Exhaustive Concordance for additional background information. The Digital-AV has, at most, four Strong's numbers per English word in the Old Testament. By contrast, there are at most, three Strong's numbers per English word. To maintain a fixed length record format, four slots allotted.

Release Version: 3.9.11

VERSION IDENTIFIERS

Digital-AV SDK: Ω3911

SDK Document: Ω3911

The Ω-series releases eliminate the AV-Verse index and place that information directly in the Written content records instead. Indexing into Written from Chapter provides verse coordinates and word counts. Navigating to subsequent verses is accomplished via the word-count for the verse. The first word always contains the word count of the verse; each subsequent word contains a countdown until one (i.e. that last word of the verse is marked with a *:*:1)

Word Key & Capitalization Field

Description	Bit Pattern (Hex)
English Word	0x3FFF (mask for lexicon)
1 st Letter Cap	0x8000 (example: Lord)
All Letters	0x4000 (example: LORD)

apply capitalization rules to the lexical word. 0x8___ means to capitalize the first letter of the word (e.g. Lord). 0x4___ means to capitalize all letters of the the word (e.g. LORD). Clearly, in English, the first letter of the first word of a sentence is capitalized, and these bits facilitate all such capitalization rules. When no bits are set, this indicates that the word should be represented exactly as it appears in the lexicon. The remaining 14-bits are referred to as the **Word Key** (a lookup key into the Lexicon). The next field is the **Punctuation** byte. Each word can be preceded by punctuation (e.g. an open parenthesis). More often, punctuation follows the word. The **Punctuation** byte also contains possible **Decoration**. Decoration includes italicized words, and words spoken by Jesus, which some bibles represent as red-colored text. The field is entirely bitwise and many forms of punctuation and decoration can simultaneously apply to a single word in the text.

The next sixteen bits can be thought of as two distinct fields: the first 2 bits, **Caps**, identify whether to

Punctuation & Decoration

Description	Bits

Transition bits are a composition of Verse-Transitions and Segment-Markers. These represent a compact mechanism for data file traversal, obviating the need for leveraging additional index files. The five left-most bits mark book, chapter, and verse transitions. The three right-most bits mark linguistic segmentation [sentence and/or phrase] boundaries. These boundaries are based upon verse transitions and punctuation.

Verse Transitions

Description	5-bits

Digital AV SDK – Record layouts & Content inventory

Release Version: 3.9.11

VERSION IDENTIFIERS

Digital-AV SDK: Ω3911

SDK Document: Ω3911

Person/Number (4 bits)

Description	Left-Most Nibble
Person bits	0x3--- (0b--11)
Number bits	0xC--- (0b11--)
Indefinite	0x0--- (0b--00)
1 st Person	0x1--- (0b--01)
2 nd Person	0x2--- (0b--10)
3 rd Person	0x3--- (0b--11)
Singular	0x4--- (0b01--)
Plural	0x8--- (0b10--)
WH*	0xC--- (0b00--)

PN+POS(12) is a sixteen bit field with the left-most nibble representing Person Number (PN). PN applies to pronouns and verb casing. Early Modern English was richer than our English today, with additional pronouns and verb cases for Second-Person-Singular and Third-Person-Singular. The Digital-AV captures and preserves all such case markings. For instance, **thy** is second-person singular whereas Early Modern English **you** is always plural form of this pronoun. The SDK encodes the markings for both person and number using the binary representation depicted in the table to the right. Similarly, remaining bits provide part-of-speech markers.

POS (12 bits)

NounOrPronoun	0x-03-
Noun	0x-01-
Noun: unknown gender	0x-010
Proper Noun	0x-03-
Pronoun	0x-02-
Pronoun: Neuter	0x-021
Pronoun: Masculine	0x-022
Pronoun: Non-feminine*	0x-023
Pronoun: Feminine	0x-024
Pronoun/Noun: Genitive	0x-0-8
Pronoun: Nominative	0x-06-
Pronoun: Objective	0x-0A-
Pronoun: Reflexive	0x-0E-
Pronoun: no case/gender	0x-020
Verb	0x-1--
to	0x-200
Preposition	0x-400
Interjection	0x-800
Adjective	0x-A00
Numeric	0x-B00
Conjunction	0x-C0-
Determiner	0x-D0-
Particle	0x-E00
Adverb	0x-F00

The twelve POS bits [POS(12)] provide bitwise information on the word usage in the context of this verse. The table to the left shows the meaning of the various bits.

There is an additional POS(32) field that has much greater fidelity on the part-of-speech for the word. POS(32) is a five-bit encoding of a human readable string. See the section labeled “Additional notes about Part-of-Speech in Digital-AV” for additional details.

The final field is the lemmatization of the word. If the 0x8000 bit is set for the Lemma, it can be looked up in the OOV-Lemmata. Otherwise, it can be looked up in the Lexicon. Incidentally, the Lemma field never applies capitalization to lemma fields. Therefore, this does not conflict with capitalization rules for the word.

* **his** is used ambiguously in the Authorized Version for third-person-singular pronouns. **his** is either masculine or neuter (**its** appears just once in the sacred text). Therefore, **his** can neither be uniformly marked as masculine, nor neuter. Instead, we mark the genitive pronoun **his** as non-feminine.

Digital AV SDK – Record layouts & Content inventory

Release Version: 3.9.11

VERSION IDENTIFIERS

Digital-AV SDK: Ω3911

SDK Document: Ω3911

Book content provides indices into Chapter content, Written content. It also provides chapter-counts and word-counts (for each of the sixty-six books of the bible). It reserves a fixed sixteen-byte field for the book-name, a fixed nine-byte field (2+3+4) for 2-character, 3-character, and 4-character abbreviations. The remaining nine bytes are a comma-delimited list of any additional alternate abbreviations.

Book Content (48 bytes)

Book Number <i>byte</i>	Chapter Count <i>byte</i>	Chapter Index <i>uint16</i>	Writ Count <i>uint16</i>	Writ Index <i>uint32</i>	Book Name 16 bytes (utf8)	Abbreviations (utf8)	
						a2 a3 a4 (12 bytes)	Alternates (10 bytes)
0	0	0	0	3911	Omega 3.9.11----	39-o39-Ω39	-----
1	50	0	38262	0	Genesis-----	Ge-Gen-Gen--	Gn-----
2	40	50	32685	38262	Exodus-----	Ex-Exo-Exod-	-----
3	27	90	24541	70947	Leviticus-----	Le-Lev-Lev--	Lv-----
66	22	1167	11995	777656	Revelation-----	Re-Rev-Rev--	-----

The dashes (-) represent zero ('\0'). The nine byte field above, namely "a2 a3 a4" comprises 2-character, 3-character, and 4-character abbreviations. Note that the format now contains 67 records instead of 66. The zeroth record contains metadata about the revision and conveniently makes record #1 correspond to book #1.

Digital AV SDK – Record layouts & Content inventory

Release Version: 3.9.11

VERSION IDENTIFIERS

Digital-AV SDK: Ω3911

SDK Document: Ω3911

Chapter Content (6 bytes)

Record # 0 bits	Writ Index Uint16	Writ Count uint16	Book Num byte	Verse Count byte
0x000 (genesis:1)	0	797	1	31
0x001 (genesis:2)	797	632	1	25
0x002 (genesis:3)	1429	695	1	24
	. . .			
0x4A2 (revelation:20)	10196	477	66	15
0x4A3 (revelation:21)	10673	749	66	27
0x4A4 (revelation:22)	11422	573	66	21

NOTE:

Chapter content differs significantly from earlier revisions, as it now includes book number and verse count, superseding the Verse-Index found in the earlier Z-Series releases of the SDK. In the Omega SDK, verse look-up is performed using the WritIndex and referencing the B:C:V:W field of Written content.

Digital AV SDK – Record layouts & Content inventory

Release Version: 3.9.11

VERSION IDENTIFIERS

Digital-AV SDK: Ω3911

SDK Document: Ω3911

Lemmata content originally appeared in the 2017 Edition of the SDK. The original version obtained Lemmata from the NLTK Python library. Now Lemmata are obtained from the MorphAdorner Java service (MorphAdorner also performs all of the POS tagging; This Java reference is performed during SDK compilation; a Java runtime dependency does not exist). Incidentally, each Lemma ordinarily maps to multiple English words or lexemes, (e.g. ‘be’ is the lemma of ‘are’, ‘were’, ‘is’, ‘art’, ‘wast’, and ‘be’). Interestingly, many words, for example ‘run’, are not constrained to a single uniform POS tag. Consequently, Lemmata lookup requires the POS tag. Successful lookups into Lemmata result in a list of WordKeys or OOVKeys (When a Lemma is OOV , it cannot be found in the Lexicon, but it can be found in the OOV-Lemmata table).

Lemmata Content (variable length records)

Part-of-Speech (POS32): uint32	Word Key uint16	PN+POS12 bits: uint16	Count uint16	Lemmata Array Uint16[] (Word or OOV keys)
0x00000036	0x0001 (a)	0x0F00	1	0x0001

VERSION IDENTIFIERS

Digital-AV SDK: Ω3911

SDK Document: Ω3911

The Lexicon provides both original and modern orthographic representations for each lexeme identified in the Written content; and it includes a search representation, stripping out all hyphens. What follows are an array of associated Part-of-Speech (POS). This is a 5-bit encoded value. A reference implementation for decoding this POS value into a human readable POS string can be found in the github repo.

Lexicon Content (variable length records)

Rec # (0 bits)	Entities uint16	Size uint16	POS[0] uint32	POS[1] uint32	POS[2] uint32	...	POS[n-1] uint32	Search char []	Display char []	Modern char []	
0	0xFFFF	n=2	12567	0x3112							metadata
1	0x0000	n=4	0x00000094	0x00000036	0x0000000A		0x80004206	a			Entities = { } dt, av, j, pp-f
2	0x0000	n=3	0x01074F9C	0x0000000A	0x01073F9C			i			Entities = { } pns11, j, pno11
3	0x0000	n=1	0x000002A8					o		oh	{ } oh
...											
366	0x8009	n=2	0x00003A1C	0x000740FC				adam			Entities = {Man, City} np1, npg1
...											
1311	0x0000	n=2	0x01073FBC	0x0000000A				thou		you	Entities = { } pns21, j
...											
12567	0x0000	n=1	0x0000000A					Mahershal alhashbaz	Maher- shalal- hash-baz		Entities = { } j

Entities = {Hitchcock=0x8000, men=0x1, women=0x2, tribes=0x4, cities=0x8, rivers=0x10, mountains=0x20, animals=0x40, gemstones=0x80, measurements=0x100}

NOTE: AV-Lexicon differs from Z14 release: it inserts a zeroth-record, making lex-key equal to record-index. It also differs by omitting the marker/final record after record #12567, as did the Z14 release. Otherwise, they are identical.

Additional notes about Part-of-Speech in Digital-AV

Both the PN+POS(12) field and the POS(32) field are found in Written content. And both represent Part-of-Speech, in different, but related manners. POS(12) is entirely bitwise, and therefore easier to make programmatic determinations based upon that field. POS(32) is a 5-bit encoded string. Decoding the 32-bit value into a string can be performed using the reference code cited on this page below. POS tagging was extracted from Morph-Adorner (also cited below). POS(12) is derived both from the MorphAdorner tag and innate knowledge in the Digital-AV compiler of pronouns and morphology. POS(32) is an encoded human-readable string. An earlier version of the SDK contained a HashMap, mapping each POS(32) value into a collection of POS(12) values. However, that file was deemed incomplete and has been eliminated from the SDK. That mapping might be useful, but is easily inferred from Written content. AV-Lexicon contains only POS(32) references, and no POS(12) references.

In short, the PN+POS(12) field is more granular and has a bitwise representation. Contrariwise, the encoded 32-bit POS fields have far more fidelity, but require decoding to expose their string representation.

For more information, see:

- <https://github.com/kwonus/Digital-AV/blob/master/z-series/Part-of-Speech-for-Digital-AV.pdf>
- <https://github.com/kwonus/AVXText/blob/master/FiveBitEncoding.cs> [*method signature: **string** DecodePOS(**UInt32** encoding)*]

Names Content (variable length records)

uint16	1 st Meaning	Delimiter	2 nd Meaning	Delimiter	3 rd Meaning	Delimiter	...
Lexicon WordKey for 'Aaron' (0x05AC)	a teacher		lofty		mountain of...	\0	
Lexicon WordKey for 'Abaddon' (0x14DC)	the destroyer	\0					
Lexicon WordKey for 'Abagtha' (0x14DD)	father of the...	\0					
...							

Names Content is a binary representation of “Hitchcock's Bible Names Dictionary”, authored by Roswell D. Hitchcock in 1869. The difference here is that it is integrated by indexing with the word-key found in AV-Lexicon.

Phonetic Content (variable length records; one record for all lexicon entries and all OOV lemmata)

WordKey uint16	1 st IPA Variant	Delimiter	2 nd IPA Variant	Delimiter	3 rd IPA Variant	Delimiter	...
Lexicon WordKey for 'a' (0x0001)	'eɪ	/	ə	\0			
...							
Lexicon WordKey for 'Aaron' (0x05AC)	'ɛɹən	\0					
...							
Lexicon WordKey for 'baptist' (0x1578)	'bæptəst	/	'bæptɪst	\0			
...							
Lexicon WordKey for 'receive' (0x1B02)	ɹə'siv	/	ɹi'siv	/	ɹɪ'siv	\0	
...							
OOV key for 'aid' (0x8301)	'eɪd	\0					
...							
OOV key for 'covenantbreaker' (0x8F01)	'kəvənənt'breɪkə	\0					
...							

American phonetic representations are provided for all entries in the lexicon and all OOV lemmata in the Phonetic Content payload. Most phonetic representations are provided in IPA. Constructed IPA representations (lexical items that are not found in the file named en_US.txt²) may contain NUPhone³ representations instead of IPA.

² En_US.txt can be found at https://github.com/open-dict-data/ipa-dict/blob/master/data/en_US.txt. This file is used to look up strings and substrings to generate IPA.

³ NUPhone representation is described at <https://github.com/kwonus/NUPhone/blob/main/NUPhone.md>

OVERALL PROJECT STATUS:

It's an exciting time at AV Text Ministries, and if you want to lend a hand. Let us know your technical skills and interests and we can help jumpstart you onto the team. We are embarking on brand-new support for Rust. Currently, AV Text Ministries is 100% volunteer, so if you don't just have passion about the mission as your raw motivation, it might not be the best fit.

Finally, on the non-technical side of things, we would certainly welcome a ministry sponsor that would want to place AV Text Ministries under the banner of their own local church ministry. Check <http://avtext.org> to discover our overall vision.

HOW THE DIGITAL-AV "PLATES" ARE AUTHORED:

Initially, various publicly available KJV texts were parsed and dutifully compared (comparing scripture with scripture [1 Corinthians 2:13]). That work produced the freeware program, AV-1995 for Windows; it was written in Delphi/Pascal and was maintained until the AV-2011 release. In 2008, the initial Digital-AV SDK was conceived and produced, harvesting much of the inner workings of AV-2008 and utilized RemObjects Oxygene/Pascal as the development platform. It was released as open source. Later, AV-2011 was "compiled" using AV-2008 as a baseline. Subsequently, the 2017/2018 Editions were "compiled" using AV-2011 as a baseline. The Z07 release of the SDK were baselined from AV-2018 edition using the K817 release. C# is now the programming language of the SDK compiler; and the ancient pascal sources were finally retired (replaced by C# sources) in 2018. The SDK-compiler uses MorpAdorner⁴ (written in Java 1.6), along with the NUPOS⁵ tag-set. NLTK⁶ (Python) is used when MorphAdorner encounters a word out of its vocabulary. Java and Python dependencies are not exhibited in the delivered SDK (They are only part of the compilation process for the published SDK).

The Z-Series introduced a new versioning scheme, but the content itself was mostly unchanged from the 2018 SDK Release. Initially, the Omega SDK versions were compiled using the latest Z-Series release as a baseline. As of Omega 3.5, the previous 3.2 Omega release as its baseline. Omega 3.9 is built from the 3.2 Omega release.

Only the <http://github.com/AV-Text/AVX> repository has the Omega 3.5 and 3.9 releases. Incidentally, the Omega releases were inspired by the simplicity of utilizing Google FlatBuffers: why mess with a bunch of files when we can mess with just one? The Z-Series assets are no longer being maintained. However, they can still be utilized as most content is cut from the same cloth.

SDK Document: Ω3911

LICENSE REQUIREMENT:

- In order to comply with the MIT-style open-source license, please include AV-License.txt with your distribution of any file identified in this SDK. The text of that file, as of 2023, is provided also at the bottom of this page.

All SDK artifacts are on github.com:

<https://github.com/AV-Text/AVX>

IMPROVEMENTS & CAVEATS:

- Underlying SDK formats have stabilized in the Z-series and Ω-series editions.
- The huge difference between the Z-series and Ω-series editions is that Omega edition utilizes a single file for deserialization.
- Ω32 release introduces revised Written, Book, and Chapter content
- Ω32 eliminates discrete content. Instead, that is provided directly in the Written content.
- Ω-series editions replaces the AV-Inventory file with Directory content, which is the first data payload of the new deserialization file.
- The name of the serialization file is **AVX-Omega.data**; and **AVX-Omega.md5** contains a hash of the data file.
- For the most part, the Omega releases share most of the same formats as the earlier Z-Series SDK. Ω35+ is the recommended SDK for future development.
- Hashing values in Directory & total-verse-counts for each Book were incorrect in Ω32. This necessitated the Ω35 release. Only Directory & Book content were revised in the Ω3507 release. Directory & Book content were further revised in the Ω3911 release [The Ω3507 is now deemed as an alpha release and should no longer be utilized. Ω3911 is a superset of the Ω3507 release, with identified bugs fixed].

ADDITIONAL RELEASE NOTES:

- Digital-AV revision numbers use a four-digit character sequence, (alpha/beta releases use three-digits and an alpha or beta Greek letter suffix/subscript). The most recent revision numbers begin with Ω. The next two characters represent year and month of the revision. The character sequence is either **Ωymdd** or **Ωymdd_α**; **y** represents the year, and **m** represents the month. **y** encodes the year as a single base-36 digit; For example, (y=0) represents 2020; (y == 3) represents 2023; (y == 5) represents 2025; (y == A) represents 2030; (y == F) represents 2035; (y == Z) represents 2055. With respect to months, digits 1 through 9 are as expected; (m == A) is October; (m == B) is November; and (m == C) is December. A two-digit day of the month follows. If a Greek letter subscript appears in the version number (α or β), then this indicates an alpha or beta release.
- Two revision numbers are provided in the specification: The Digital-AV SDK revision (aka, the “plate” revision) is the most significant as it identifies the actual serialization file. There is also a distinct and separate revision number for the document itself. Finally, when appendices are included, those also have distinct revision numbers.
- Introduced in the Ω3905 revision is phonetic representations for all modern lexical items and all OOV lemmata. This can be used as a lookup for any keyed string provided in the Lexicon Content and in the OOV-Lemmata Content

Digital AV SDK – C# Foundational Support

Version: 3.9

VERSION	IDENTIFIER
C# Support :	$\Omega 3910_a$

COMING SOON!!!

With the Ω -series SDK, we open just a single binary file to extract all SDK content.

C# sources can be found in the Digital-AV/omega/foundations/csharp/ folder on GitHub. As with the other foundational support, Written content is segmented into 66 different arrays and placed in the Book index/content (one slice for each book of the bible).

The code is currently in development, but leverages the rock solid foundation of decades of earlier deployments of the Digital-AV SDK.

The fundamental difference here with the companion project AVXText, is that the current AVXText github bundles the interpreter with the bible content for search capabilities. This is no longer necessary as Quelle can serve that purpose, while these sources are dedicated only for deserialization, validation, and content delivery. AVXText will eventually be replaced with an integrations of C# Foundation with Quelle which leverages a Parsing Expression Grammar (PEG) library called Pinshot-Blue and a parse interpreting service called Blueprint-Blue.
